## 6.1 INTRODUCTION

The amorphous thin films of  $\text{Sb}_2\text{Se}_3$  are prepared by various technique [1 - 8] but no report is available on the preparation of polycrystalline  $\text{Sb}_2\text{Se}_3$  thin films from a non - aqueous medium. The present chapter reports on the deposition of  $\text{Sb}_2\text{Se}_3$  thin films from non - aqueous medium and study of their structural, optical and electrical properties. Effect of change of Se source on the film properties has also been discussed.

## 6.2 EXPERIMENTAL

$\text{Sb}_2\text{Se}_3$  thin films have been deposited by the spray pyrolysis technique, as discussed in section 3.2.1.1 and by using selenium dioxide [ $\text{SeO}_2$ ] and selenourea [ $\text{CSe}(\text{NH}_2)_2$ ] as Se source respectively.

### 6.2.1 *Thin film deposition*

#### *Substrate cleaning*

The substrate cleaning procedure discussed in section 3.1.2.2 is used to clean the glass substrates.

#### 6.2.1.1 *Film deposition using $\text{SeO}_2$*

The initial ingredients used to prepare  $\text{Sb}_2\text{Se}_3$  thin films are as follows :

- i) A.R. Grade, antimony trichloride [ $\text{SbCl}_3$ ] supplied by s.d. fine Chem., Limited, Boisar, Mumbai- 2.
- ii) A.R. Grade, selenium dioxide [ $\text{SeO}_2$ ] supplied by Qualigens Fine Chemicals, Mumbai.

iii) A.R. Grade, acetic acid glacial supplied by Qualigens Fine Chemicals, Mumbai.

iv) A.R. Grade, formaldehyde supplied by Qualigens Fine Chemicals, Mumbai.

The solutions of antimony trichloride ( $\text{SbCl}_3$ ) and  $\text{SeO}_2$  were prepared by dissolving the appropriate amount of the salts in acetic acid and formaldehyde, respectively. These equimolar solutions were mixed together in the appropriate volumes to obtain Sb : Se ratio as 2 : 3. The whitish turbidity resulted due to direct mixing of  $\text{SbCl}_3$  and  $\text{SeO}_2$  can be redissolved by the addition of excess acetic acid (glacial). The orange coloured films were prepared by spraying the clear solution onto the preheated glass substrates.

#### *Spray rate*

During the  $\text{Sb}_2\text{Se}_3$  film deposition the spray rate was maintained to be 14  $\text{cc min}^{-1}$  [9].

#### *Substrate temperature*

A mixed solution of  $\text{SbCl}_3$  and  $\text{SeO}_2$  of concentration 0.1 M was sprayed with spray rate of 14  $\text{cc min}^{-1}$  onto the set of glass substrates maintained at temperatures from 150 °C, at the interval of 25 °C, to 250 °C. The structural and electrical analyses of these films reveal that the as deposited films are amorphous in nature, while only the film deposited at 200 °C and heat treated in  $\text{N}_2$  atmosphere at 325 °C are polycrystalline. The electrical resistivity of these films has relatively higher conductivity as compared to the films deposited at other substrate temperatures and thus leads to the optimized substrate temperature [9].

### *Solution concentration*

The  $\text{Sb}_2\text{Se}_3$  thin films were prepared at solution concentration from 0.025 M to 0.1 M at optimised substrate temperature of 200 °C with spray rate of 14 cc min<sup>-1</sup>. The structural and electrical characterization of annealed films show that the films deposited at concentration of 0.025 M are relatively higher crystalline and show relatively higher conductivity than the films prepared at other concentrations. 0.025 M is, therefore, taken as optimized solution concentration [10].

#### *6.1.2.2 Annealing of the $\text{Sb}_2\text{Se}_3$ thin films*

Annealing of  $\text{Sb}_2\text{Se}_3$  thin films is carried out in  $\text{N}_2$  atmosphere at temperature of 325<sup>0</sup> C for 2 hours as discussed in section 3.2.1.5.

#### *6.2.1.3 Film preparation using selenourea [ $\text{CSe}(\text{NH}_2)_2$ ]*

Solutions of  $\text{SbCl}_3$  and  $\text{CSe}(\text{NH}_2)_2$  (A.R. Grade supplied by Qualigens Ltd.) were prepared in acetic acid (glacial). The equimolar solutions of  $\text{SbCl}_3$  and  $\text{CSe}(\text{NH}_2)_2$  were mixed together in appropriate volume to obtain Sb : Se ratio as 2:3. The films were prepared by spraying the mixed solution (28 cc) onto the preheated glass substrates. The spray rate was maintained at 3 cc min<sup>-1</sup>. The substrate temperature and the solution concentration were optimized as 150<sup>0</sup> C and 0.01 M respectively [11]. The films were uniform, pinhole free, adherent and blackish brown in colour.

## 6.2.2 CHARACTERIZATION OF $\text{Sb}_2\text{Se}_3$ THIN FILMS

The  $\text{Sb}_2\text{Se}_3$  films prepared using  $\text{SeO}_2$  and  $\text{CSe}(\text{NH}_2)_2$  at their respective optimized parameters were characterized by using X-ray diffraction (XRD), scanning electron microscopy, optical absorption, dark resistivity and TEP measurement techniques.

### 6.2.2.1 X-ray diffraction (XRD)

XRD studies were carried out as discussed in section 3.2.2.1.

### 6.2.2.2 Scanning electron microscopy (SEM)

SEM studies were carried out as discussed in section 3.2.2.2.

### 6.2.2.3 Optical absorption

To carry out the optical absorption studies the procedure discussed in section 3.2.2.3 was adopted.

### 6.2.2.4 Electrical Resistivity

To study the electrical characterisation of the films, dark resistivity measurements were carried out using two point d.c. probe method in the temperature range 300 to 500K. The details of experimental setup are discussed in Section 3.2.2.4.

### 6.2.2.5 Thermoelectric power (TEP)

The details of the experimental setup of TEP are given in section 3.2.2.5.

## 6.3 RESULTS AND DISCUSSION

In a spray pyrolysis method, the thermal energy for the decomposition and subsequent recombination of the species and the sintering and recrystallisation of the crystallites, is provided by the hot substrates. It is different for the different materials and the solvents used in the deposition process. Therefore the decomposition temperatures for  $\text{Sb}_2\text{Se}_3$  thin films are different for two different Se sources and two different solvents, e.g. for  $\text{SeO}_2$  source in aqueous medium, it is  $300^\circ\text{C}$  (Chapter V), for  $\text{CSe}(\text{NH}_2)_2$  source in aqueous medium, it is  $275^\circ\text{C}$  (Chapter V), for  $\text{SeO}_2$  source in non-aqueous medium, it is  $200^\circ\text{C}$  and for  $\text{CSe}(\text{NH}_2)_2$  source in non - aqueous medium, it is  $150^\circ\text{C}$ .

The thickness of the prepared films was determined using relation 2.1. The density of deposited material is taken to be  $5.81\text{ gm cc}^{-3}$  [12]. The thickness of the  $\text{Sb}_2\text{Se}_3$  films deposited using  $\text{SeO}_2$  and  $\text{CSe}(\text{NH}_2)_2$  were found to be  $1.3\ \mu\text{m}$  and  $0.52\ \mu\text{m}$  respectively.

### 6.3.1 X-ray diffraction (XRD)

XRD patterns of  $\text{Sb}_2\text{Se}_3$  thin films prepared using two different Se sources are studied in order to reveal their structural aspects.

#### *Films using $\text{SeO}_2$*

The appearance of the broad X-ray spectrum, as shown in Fig. 6.1 (a) for the films suggests the amorphous nature of the deposited material.

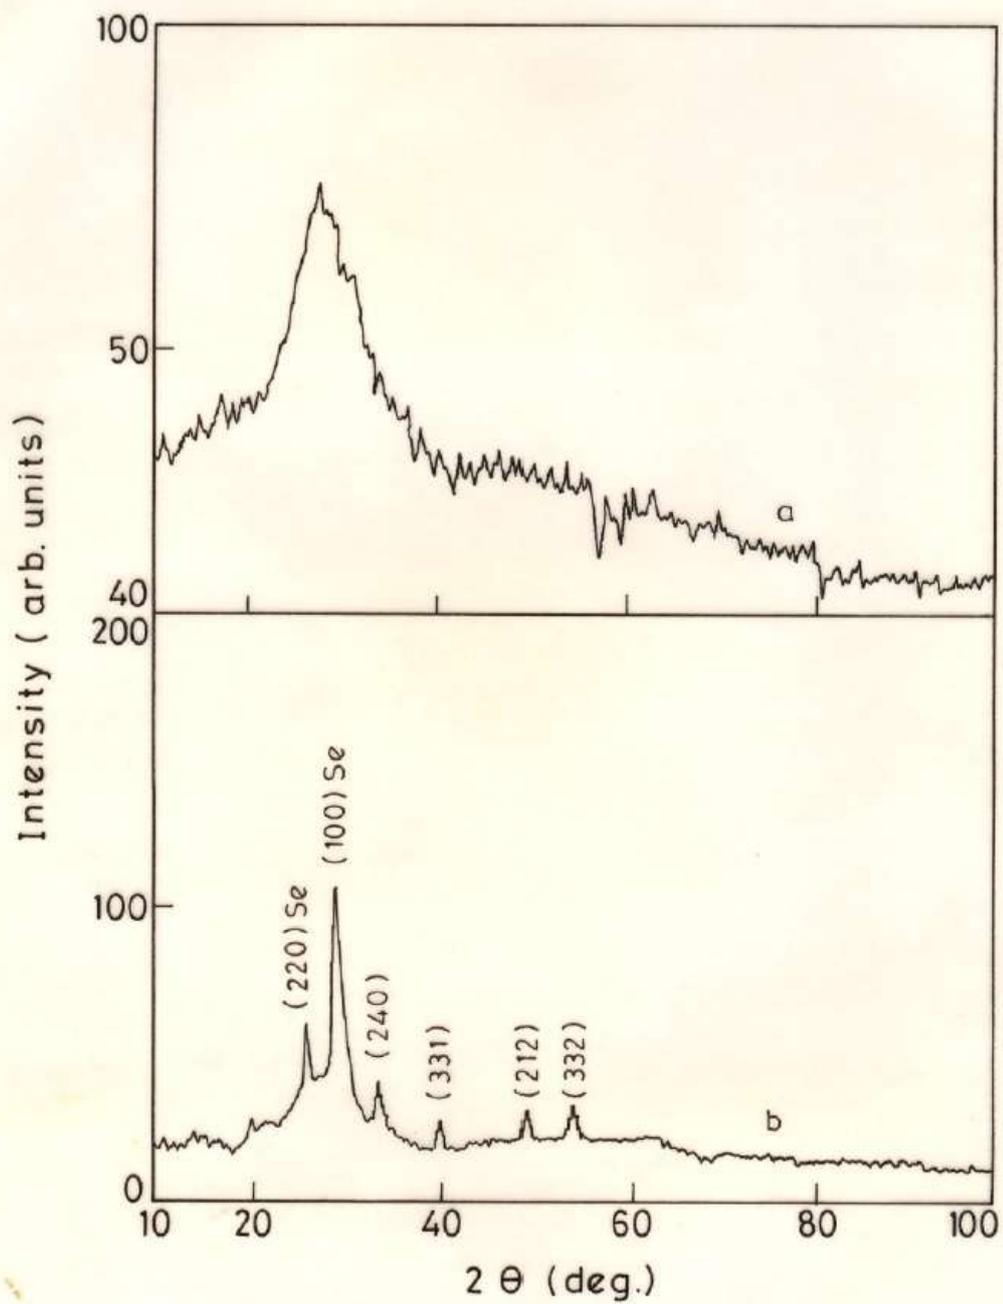

Fig. 6.1 : XRD patterns for the  $\text{Sb}_2\text{Se}_3$  thin films prepared using  $\text{SeO}_2$ ; a) as-deposited and b) annealed.

### *Films using CSe(NH<sub>2</sub>)<sub>2</sub>*

Fig. 6.2 shows the XRD pattern for the Sb<sub>2</sub>Se<sub>3</sub> films prepared using CSe(NH<sub>2</sub>)<sub>2</sub> as a Se source from non - aqueous medium. The films are found to be amorphous in nature [11].

The structural difference between the Sb<sub>2</sub>Se<sub>3</sub> films prepared using CSe(NH<sub>2</sub>)<sub>2</sub> from aqueous (Chapter V) and non-aqueous media is due to the difference in stoichiometric proportion occurred; certainly due to the difference in reaction mechanisms, during pyrolytic decomposition of the Sb<sub>2</sub>Se<sub>3</sub>.

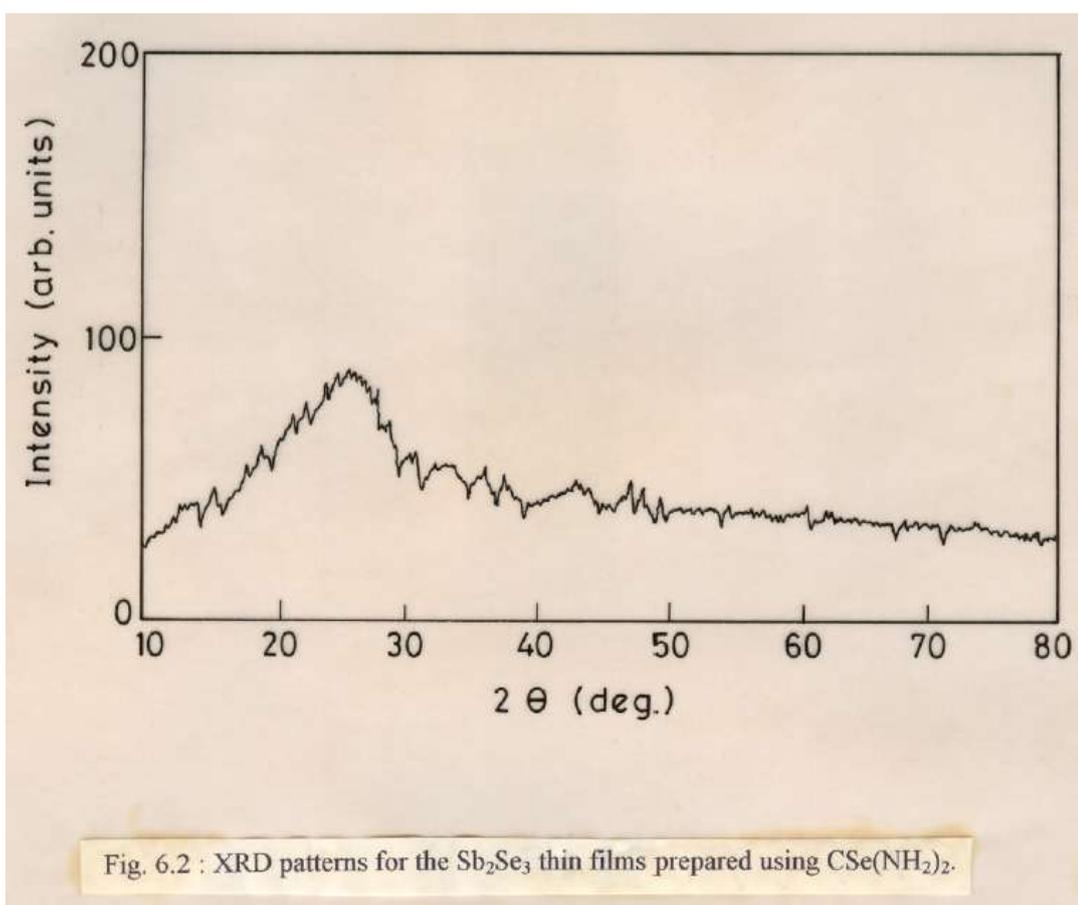

### *6.3.2 Scanning electron microscopy*

#### *Films using SeO<sub>2</sub>*

SEM micrographs of Sb<sub>2</sub>Se<sub>3</sub> thin films deposited from non- aqueous medium onto glass substrates are studied to see the surface morphology of the film. SEM micrographs of as- deposited Sb<sub>2</sub>Se<sub>3</sub> thin films are shown in Figs. 6.3 (a) and (b) for two different magnifications 2000x and 5000x respectively. The micrographs show the total coverage of the substrate by the film with rough surface morphology .

#### *Films using CSe(NH<sub>2</sub>)<sub>2</sub>*

SEM micrographs of as-deposited Sb<sub>2</sub>Se<sub>3</sub> films prepared using CSe(NH<sub>2</sub>)<sub>2</sub> are shown in Figs 6.4 (a) and (b) at two magnifications 2000x and 5000x respectively. The micrographs show holes at 5000x magnification. Incomplete decomposition of the particles at the film surface is also seen.

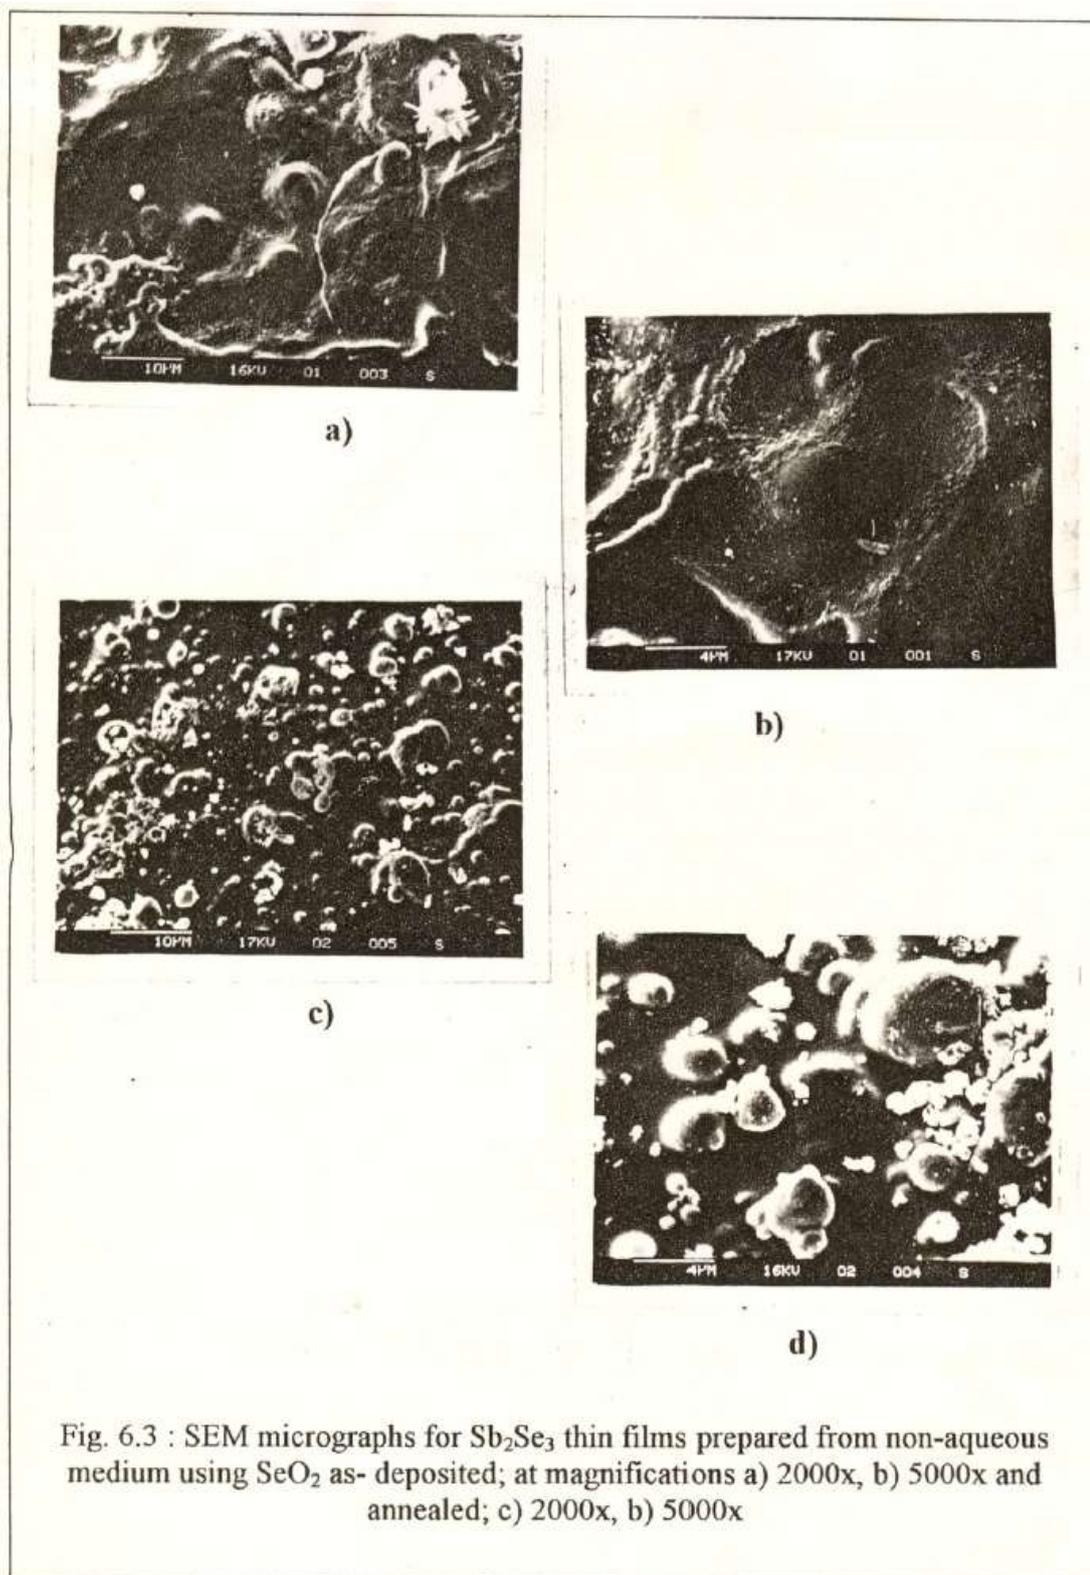

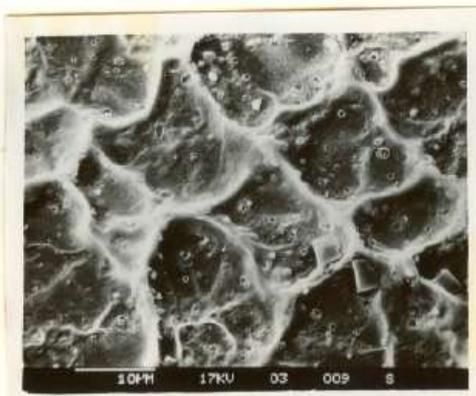

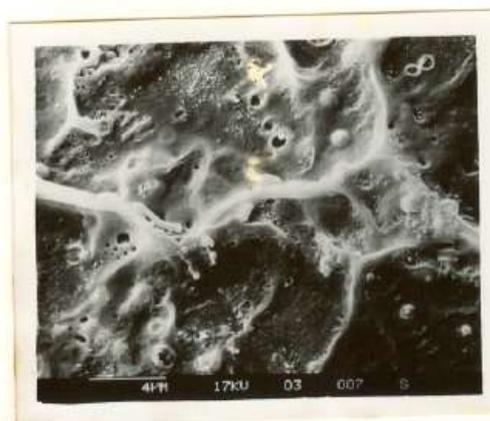

Fig. 6.3 : SEM micrographs for  $Sb_2Se_3$  thin films prepared from non-aqueous medium using  $SeO_2$  as- deposited; at magnifications a) 2000x, b) 5000x and annealed; c) 2000x, b) 5000x

a)

b)

Fig. 6.4 : SEM micrographs for  $\text{Sb}_2\text{Se}_3$  thin films prepared from non-aqueous medium using  $\text{CSe}(\text{NH}_2)_2$  at magnifications a) 2000x and b) 5000x

### 6.3.3 Optical absorption

The  $\text{Sb}_2\text{Se}_3$  films prepared using two different Se sources from non-aqueous medium are optically characterized by measuring the optical density in the wavelength range of 300 to 1200 nm.

#### *Films using $\text{SeO}_2$*

Variation of optical density ( $\alpha t$ ) with wavelength ( $\lambda$ ) for  $\text{Sb}_2\text{Se}_3$  films is shown in Fig. 6.5.  $\alpha$  is found to be of the order of  $10^4 \text{ cm}^{-1}$ . The energy dependent absorption coefficient can be expressed by the relation 2.8 for amorphous semiconductors [13 - 14] with  $n=2$ .

The absorption of photon energy for amorphous films of  $\text{Sb}_2\text{Se}_3$  have been explained by many workers [1-4, 6-7]. Figure 6.6 (a) shows the plot of  $(\alpha h\nu)^{1/2}$  versus  $h\nu$  for as deposited film of  $\text{Sb}_2\text{Se}_3$  prepared using  $\text{SeO}_2$ . The optical gap, obtained by extrapolating the straight line portion of the plot to energy axis at  $\alpha=0$ , is found to be 0.86 eV. The difference in the value of optical gap observed and reported earlier [2] may be attributed to the different mechanisms of film formation.

#### *Films using $\text{CSe}(\text{NH}_2)_2$*

Variation of optical density ( $\alpha t$ ) with wavelength ( $\lambda$ ) for  $\text{Sb}_2\text{Se}_3$  films is shown in Fig. 6.7.  $\alpha$  is of the order of  $10^4 - 10^5 \text{ cm}^{-1}$ . The exponential form of the tail, being observed, may be due to disorder and defects (e.g., gap states) in the amorphous material [9].

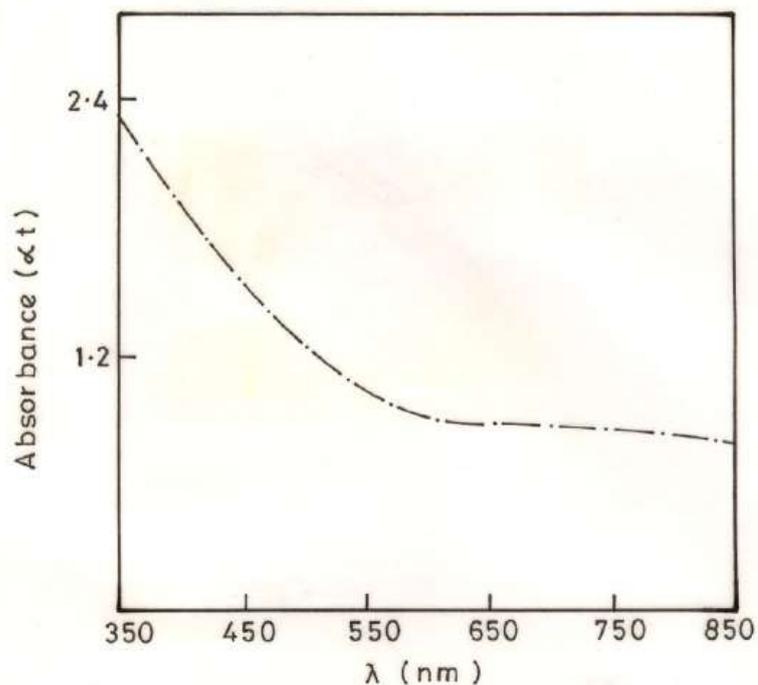

Fig.6-5 - Variation of  $\alpha t$  with  $\lambda$  for  $\text{Sb}_2\text{Se}_3$  film prepared using  $\text{SeO}_2$ .

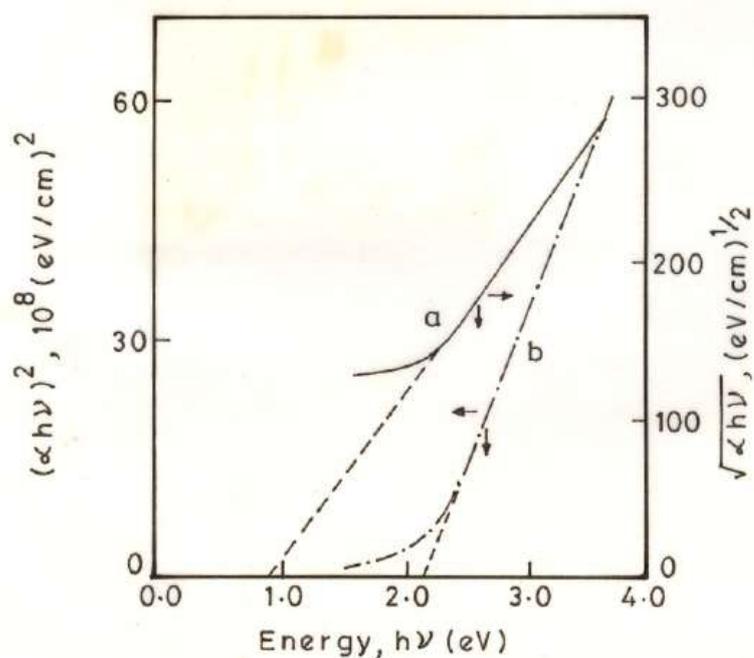

Fig.6-6 - Plot of  $(\alpha h\nu)^{1/2}$  and  $(\alpha h\nu)^2$  versus  $h\nu$  for  $\text{Sb}_2\text{Se}_3$  thin films prepared using  $\text{SeO}_2$ , a) as-deposited b) annealed.

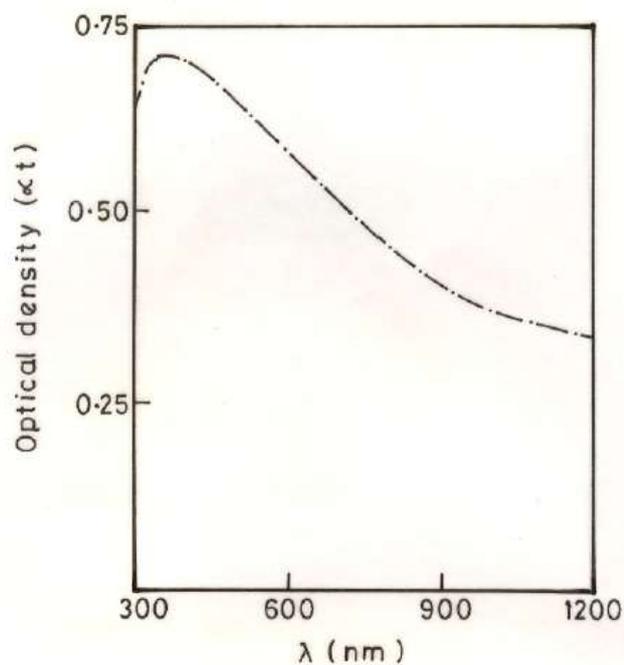

Fig.6.7 - Variation of  $\alpha t$  with  $\lambda$  for  $\text{Sb}_2\text{Se}_3$  thin film prepared using  $\text{CSe}(\text{NH}_2)_2$ .

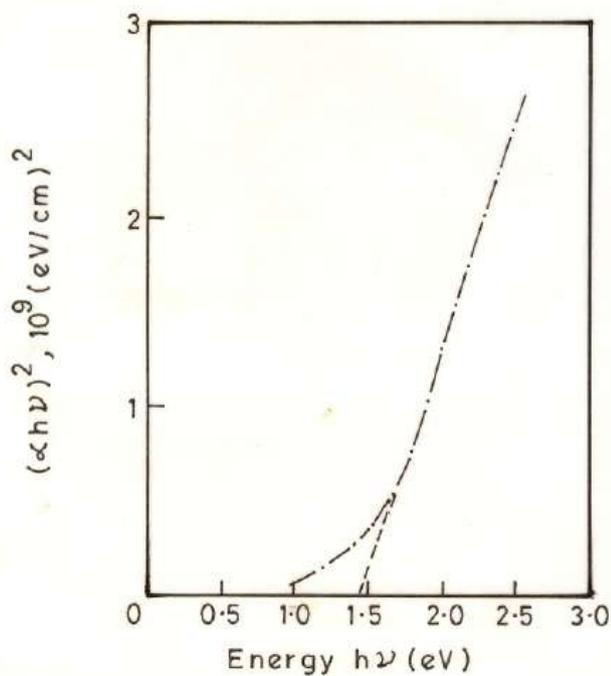

Fig. 6.8 - Plot of  $(\alpha h\nu)^2$  versus  $h\nu$  for  $\text{Sb}_2\text{Se}_3$  thin films prepared using  $\text{CSe}(\text{NH}_2)_2$ .

The absorption coefficient at absorption edge follows the relation 2.8 for amorphous semiconductor [13,14] with  $n=2$ , but for the films prepared using  $CSe(NH_2)_2$ ,  $\alpha$  follows the relation 2.8 with  $n = 1/2$ . The plot of  $(\alpha hv)^2$  versus  $hv$  is linear and is shown in Fig. 6.8. The observed optical gap is 1.45 eV [15] due to direct band transition. The difference in the optical gap of  $Sb_2Se_3$  films using two different Se sources is attributed to the different decomposition temperatures and difference in density of gap states.

#### 6.3.4 Electrical resistivity

Two point d.c. dark resistivity measurements show that the films prepared using  $SeO_2$  and  $CSe(NH_2)_2$  are highly resistive. The room temperature dark resistivity for both the films is of the order of  $10^6 - 10^7 \Omega.cm$ , similar to the result of others [3]. The high resistivity of the film may be due to discontinues, large grain boundaries and low thickness of the films.

##### *Films using $SeO_2$*

The variation of  $\log(\rho)$  with reciprocal of temperature for the as - deposited films is depicted in Fig. 6.9 (a). It has been seen that the resistivity decreases with increase in temperature and supports for the semiconducting nature of the films. The calculated activation energy for the films was 0.77 eV [9].

##### *Films using $CSe(NH_2)_2$*

The variation of  $\log(\rho)$  with  $1000/T$  for  $Sb_2Se_3$  films deposited using  $CSe(NH_2)_2$  is depicted in Fig. 6.10. Calculated activation energy for the films

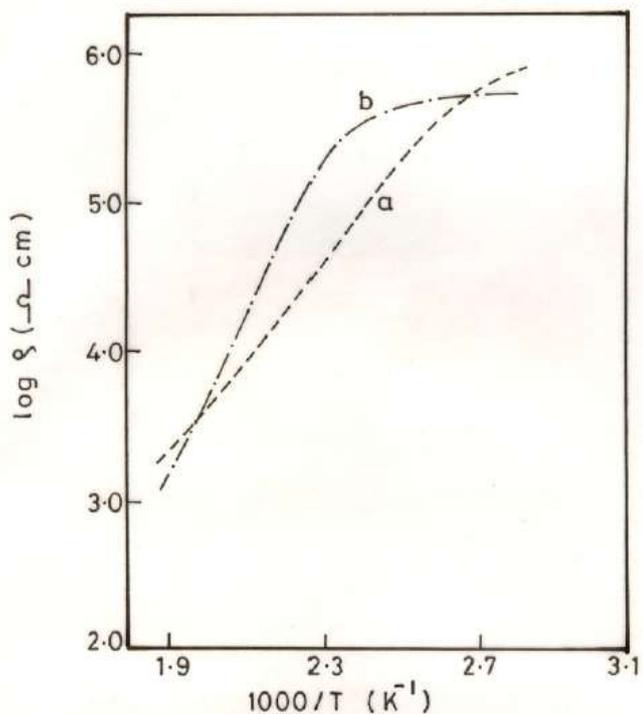

Fig.6.9 - Variation of  $\log \eta$  against  $1000/T$  for  $\text{Sb}_2\text{Se}_3$  thin films prepared using  $\text{SeO}_2$ ; a) as-deposited b) annealed.

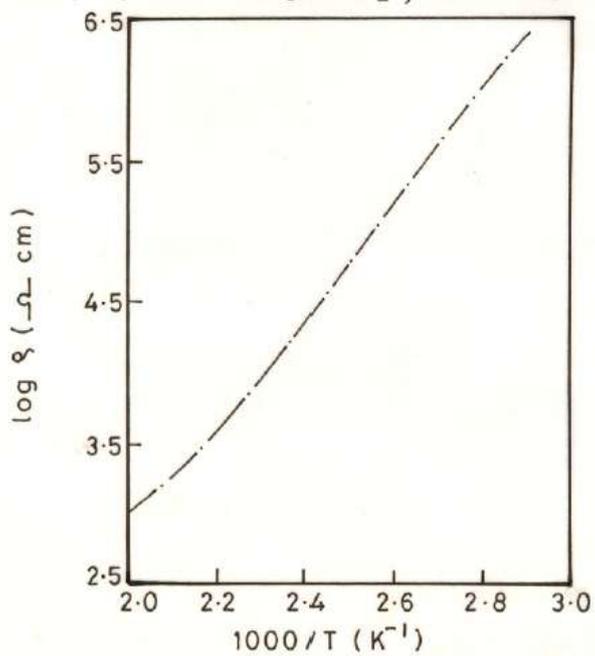

Fig. 6.10 - Variation of  $\log \eta$  against  $1000/T$  for  $\text{Sb}_2\text{Se}_3$  thin films prepared using  $\text{CSe}(\text{NH}_2)_2$ .

is 0.82 eV. The difference in observed activation energies in two cases may be due to difference in stoichiometry of the material.

### 6.3.5 Thermoelectric Power (TEP)

It is seen that the polarity of thermally generated voltage is negative towards hot end indicating that the  $\text{Sb}_2\text{Se}_3$  films prepared using  $\text{SeO}_2$  and  $\text{CSe}(\text{NH}_2)_2$  are of *p* - type conductivity.

#### *Films using $\text{SeO}_2$*

The dependence of thermoelectric e.m.f. on temperature difference is depicted in Fig. 6.11 (a). It is seen that e.m.f, first rises sharply upto the temperature difference of  $30^\circ\text{C}$  and varies linearly within  $30 - 120^\circ\text{C}$ , tending towards saturation.

#### *Films using $\text{CSe}(\text{NH}_2)_2$*

Fig. 6.12 shows the variation of thermo emf with temperature difference for the films prepared using and  $\text{CSe}(\text{NH}_2)_2$ . It is seen that the the emf varies linearly with temperature difference upto  $100^\circ\text{C}$

The difference in observed variation of emf in two cases is due to difference in the carrier concentration and mobility in two cases.

### 6.3.6 Annealing of the $\text{Sb}_2\text{Se}_3$ thin films

The  $\text{Sb}_2\text{Se}_3$  films were annealed in  $\text{N}_2$  atmosphere for a optimized time of 2 hours at an optimized temperatures of  $325^\circ\text{C}$ , to study its effect on their structural, optical and electrical properties.

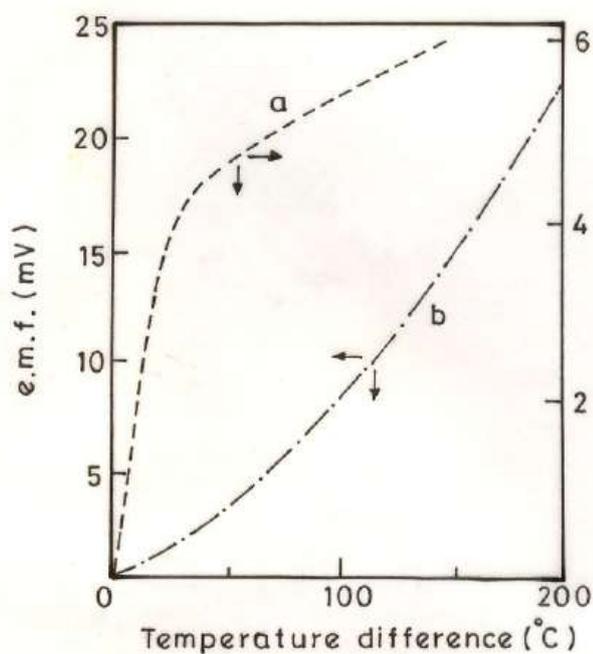

Fig.6-11 - e.m.f. versus temperature difference for  $Sb_2Se_3$  thin films prepared using  $SeO_2$ .  
a) as-deposited b) annealed .

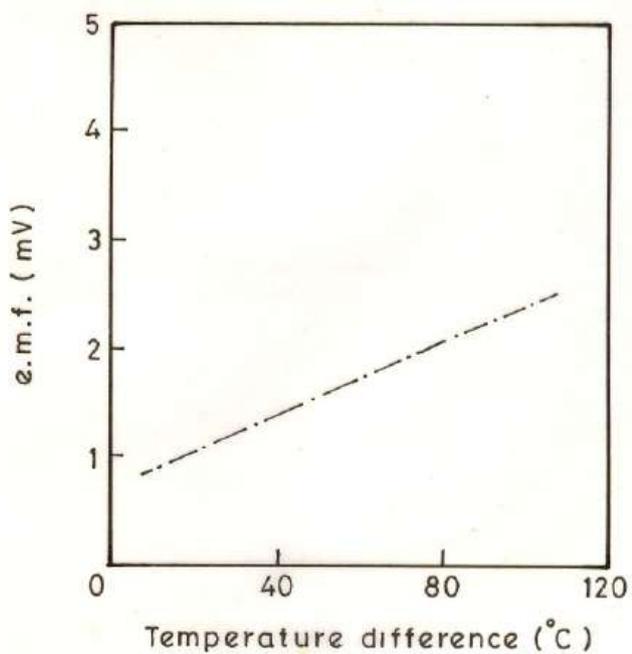

Fig. 6-12 - e.m.f. versus temperature difference for  $Sb_2Se_3$  thin films prepared using  $CSe(NH_2)_2$  .

### 6.3.6.1 Films using $SeO_2$

#### 6.3.6.1.1 X-ray diffraction

The XRD patterns of the annealed films show that the films are polycrystalline [Fig. 6.1 (b)]. Comparison of ASTM data [15] of  $Sb_2Se_3$  with the observed data of the films reveals that the observed  $d$  values match with the standard  $d$  values. This confirms the formation of  $Sb_2Se_3$  material. Table 6.2 shows the comparison of the standard  $d$  with ASTM data.

Table 1 comparison of the observed  $d$  values of  $Sb_2Se_3$  thin films with standard ASTM data

Observed $d$ values ( $\text{\AA}$ )	Standard $d$ values ( $\text{\AA}$ )	I / I <sub>o</sub> (%)	( $hkl$ ) planes
3.437	3.416	39.43	(220) Se
3.033	3.03	100.00	(100) Se
2.646	2.629	23.83	(240)
2.229	2.238	19.52	(331)
1.858	1.861	28.61	(212)
1.699	1.698	26.18	(322)

Annealing promotes fusion of small crystallites (agglomeration), thus reducing the grain boundary area, leads to the increase in grain size of the  $Sb_2Se_3$  particles.

The calculated lattice constants are found to be  $a = 11.1881 \text{ \AA}$ ,  $b = 11.2140 \text{ \AA}$  and  $c = 4.0348 \text{ \AA}$  [10] for orthorhombic crystal structure. These

values are very close to the values of lattice constants reported for single crystals of  $\text{Sb}_2\text{Se}_3$  [17].

#### 6.3.6.1.2 Scanning electron microscopy (SEM)

Fig. 6.3 (c) and (d) show the SEM micrographs of annealed  $\text{Sb}_2\text{Se}_3$  films at two different magnifications 2000x and 5000x exhibiting its microstructure. Random distribution of particles having different size are observed. The film is continuous with fine grains. Surface is rough with presence of extra particles.

#### 6.3.6.1.3 Optical absorption

The nature of the optical transition involved, for the polycrystalline film, can be determined by considering the dependence of  $\alpha$  on  $h\nu$  in equation 2.8 with  $n = 1/2$ .

In the present case the plot of  $(\alpha h\nu)^2$  vs.  $h\nu$  [Fig. 6.6 (b)] is linear, indicating that the transition is a direct one. The optical band gap  $E_g^{\text{opt}}$  is 2.14 eV due to direct transition has been observed [9]. However, for the as-deposited (amorphous) films, the optical band gap is obtained by plotting  $(\alpha h\nu)^{1/2}$  versus  $h\nu$  has been found to be 0.86 eV. This change in optical gap after annealing of the film at specific temperature may be due to (i) the change in atomic order in the amorphous phase and (ii) occurrence of ‘wrong bonds’ due to presence of 5-fold ring in amorphous structure [18].

#### 6.3.6.1.4 Electrical resistivity

The dark resistivity for the annealed film is found to be of the order of  $10^6 - 10^7 \Omega\cdot\text{cm}$  which is same as that of the amorphous film. The plot of  $\log$

( $\rho$ ) versus  $1000/T$  for annealed film is shown in Fig. 6.9 (b). It is seen that there are two regions corresponding to low and high temperatures and electrical conduction in these films can take place via two parallel mechanisms : (a) Intrinsic conduction mechanism which occurs at high temperature (above 435 K) and (b) the hopping conduction in localized states at low temperatures (below 435 K) [7]. The activation energies corresponding to the low and high temperature regions are 0.52 eV and 0.01 eV, respectively. The activation energy in high temperature region is nearly similar to the reported value [7]. However, the decrease in activation energy in low temperature region (below 435 K) for polycrystalline film indicates that the deep trapping levels have been removed by annealing the samples [19].

#### 6.3.6.1.5 Thermoelectric Power (TEP)

It has been found that the annealed  $Sb_2Se_3$  films are of  $p$ -type conductivity. The dependence of thermo e.m.f. on temperature difference is shown in Fig. 6.11 (b) which varies linearly with the temperature difference. This is attributed to the increase in carrier concentration and mobility of the charge carriers with rise in temperature.

The difference in the nature of variation in the thermally generated voltage with temperature difference for polycrystalline and amorphous films may be attributed to the relatively more ordered structure of the polycrystalline films than amorphous ones.

### 6.3.3.2 *Films using CSe(NH<sub>2</sub>)<sub>2</sub>*

Annealing of Sb<sub>2</sub>Se<sub>3</sub> thin films is carried out at temperature of 300<sup>0</sup> C in N<sub>2</sub> atmosphere for 2 hours to see the effect of annealing on the structure of the films. It is observed that there is no change in the structure of amorphous Sb<sub>2</sub>Se<sub>3</sub> thin films prepared using CSe(NH<sub>2</sub>)<sub>2</sub> from non-aqueous medium. This may be due to non stiochiometry of the deposited material.
